

On the nuclear astrophysics from astrophysics perspective

Andrzej Odrzywołek

Dept. of General Relativity & Astrophysics

22 May 2018

Why Nuclear Astrophysics?

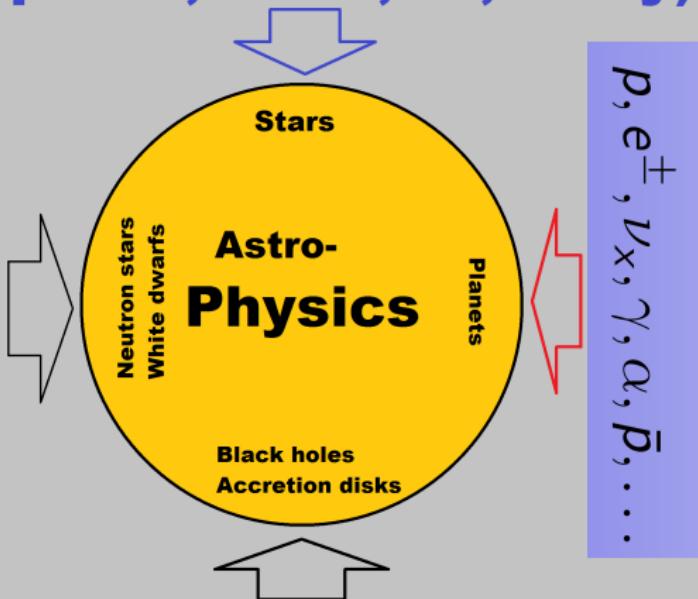

- ① Big Bang Nucleosynthesis
- ② Nuclear Evolution of the Universe (production of elements)
- ③ Stellar Amnesia (thermodynamic equilibrium)
- ④ Supernovae, Novae, Kilonovae
- ⑤ Neutrino emission, evolution of neutron excess
- ⑥ Neutron stars: interiors, pasta phases, EOS
- ⑦ Pyconuclear reactions, explosive hydrogen burning
- ⑧ Rotating liquid drop models vs rotating stars/disks
- ⑨ Extrasolar planet composition: super-Earths, blue ocean, etc.

Astronomy vs Astrophysics

Astronomy
(optical, radio, IR, X-ray)

**Neutrino
astronomy**

$\nu_e, \bar{\nu}_e, \nu_\mu, \bar{\nu}_\mu, \nu_\tau, \bar{\nu}_\tau$

**Gravitational wave
astronomy**

Big Bang Nucleosynthesis

Three stages

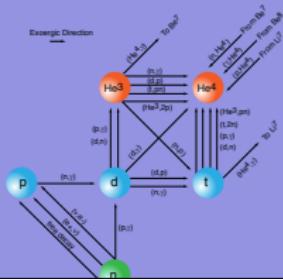

- ① p, n in thermodynamic equilibrium ($\Delta = 1.2933 \text{ MeV}$)

$$\frac{N_n}{N_p} = \frac{e^{-m_n c^2 / kT}}{e^{-m_p c^2 / kT}} = e^{-\Delta / kT}$$

- ② weak freezeout ($kT \simeq 0.7 \text{ MeV}$), neutron decay/ $d, t, {}^3\text{He}$ photodisintegration ($20kT > 2.2 \text{ MeV}$)

- ③ full nuclear reaction network in expanding matter

Weak freezeout

Proton/neutron mixture kinetics

$$\frac{dn_n(t)}{dt} + 3H(t)n_n = -\lambda_{n\nu_e} n_n + \lambda_{p\bar{\nu}_e} n_p - \lambda_{\beta^-} n_n + \lambda_{pe-\bar{\nu}_e} n_p - \lambda_{ne+} n_n + \lambda_{pe-} n_p$$

$$\frac{dn_p(t)}{dt} + 3H(t)n_p = +\lambda_{n\nu_e} n_n - \lambda_{p\bar{\nu}_e} n_p + \lambda_{\beta^-} n_n - \lambda_{pe-\bar{\nu}_e} n_p + \lambda_{ne+} n_n - \lambda_{pe-} n_p$$

$H(t)$ - Hubble „constant”; $n_n(t), n_p(t)$ - number density of neutrons and protons; λ_i - reaction rate.

All reaction rates are remarkably similar, e.g:

$$\lambda_{n\nu_e} = \frac{\ln 2}{\langle ft \rangle m_e^5} \int_{\Delta}^{\infty} \frac{(E_e + \Delta)^2 E_e \sqrt{E_e^2 - m_e^2}}{1 + e^{(E_e - \Delta)/kT}} \left(1 - \frac{1}{1 + e^{E_e/kT}}\right) dE_e$$

and except for phase-space/blocking factors can be tracked down
do **free neutron lifetime!**

Weak freezeout

Proton/neutron mixture kinetics

$$\frac{dn_n(t)}{dt} + 3H(t)n_n = -\lambda_{n\nu_e} n_n + \lambda_{p\bar{\nu}_e} n_p - \lambda_{\beta^-} n_n + \lambda_{pe-\bar{\nu}_e} n_p - \lambda_{ne+} n_n + \lambda_{pe-} n_p$$

$$\frac{dn_p(t)}{dt} + 3H(t)n_p = +\lambda_{n\nu_e} n_n - \lambda_{p\bar{\nu}_e} n_p + \lambda_{\beta^-} n_n - \lambda_{pe-\bar{\nu}_e} n_p + \lambda_{ne+} n_n - \lambda_{pe-} n_p$$

$H(t)$ - Hubble „constant”; $n_n(t), n_p(t)$ - number density of neutrons and protons; λ_i - reaction rate.

All reaction rates are remarkably similar, e.g:

$$\lambda_{\beta^-} = \frac{\ln 2}{\langle ft \rangle m_e^5} \int_{m_e}^{\Delta} \frac{(E_e + \Delta)^2 E_e \sqrt{E_e^2 - m_e^2}}{1 + e^{-E_e/kT}} \left(1 - \frac{1}{1 + e^{E_e/kT}} \right) dE_e$$

and except for phase-space/blocking factors can be tracked down
do **free neutron lifetime!**

Importance of neutron lifetime

BBN uncertainties

BBN now (could) become zero-parameter (?) model:

- ① traditional BBN free parameter, baryon-to-photon ratio PDG2015, [PDG2018, 95% CL (2σ)]:

$$\eta \equiv \frac{n_B}{n_\gamma} \simeq 6.05 \pm 0.07 \times 10^{-10}, \quad 6.2 \pm 0.4 \times 10^{-10}$$

which determine initial conditions for BBN reaction network, now known from **Cosmic Microwave Background/Planck** satellite.

- ② number of neutrino families:

$$N_\nu = 2.984 \pm 0.008$$

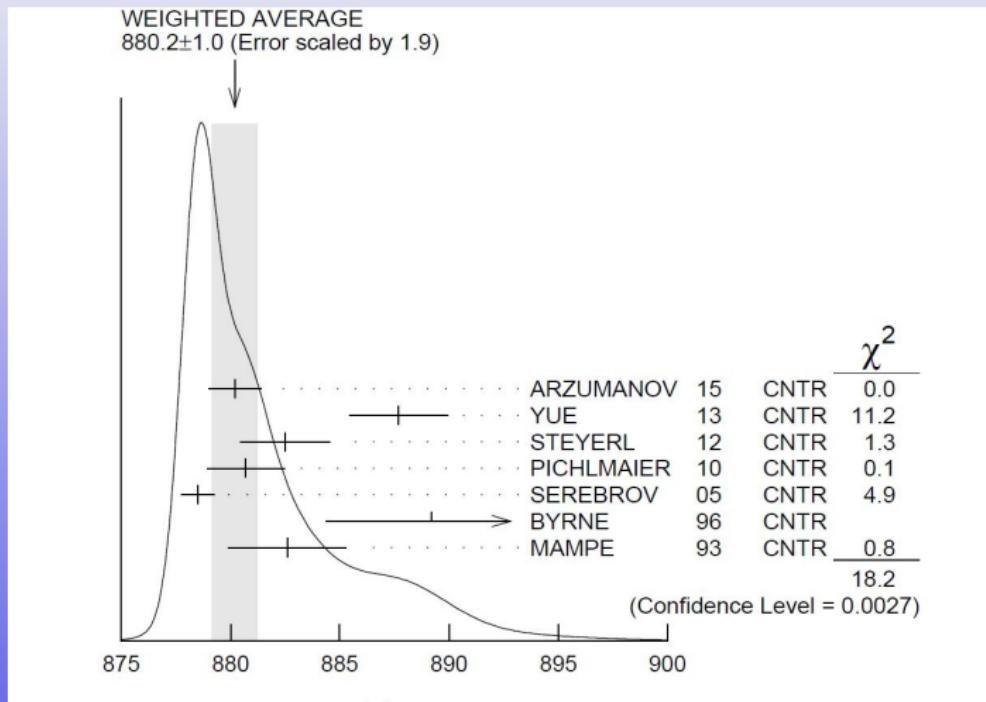

known from CERN LEP.

- ③ lifetime of neutron measured:

$$\tau_n = 880.2 \pm 1.0 \text{ seconds.}$$

Neutron lifetime

Notable BBN software

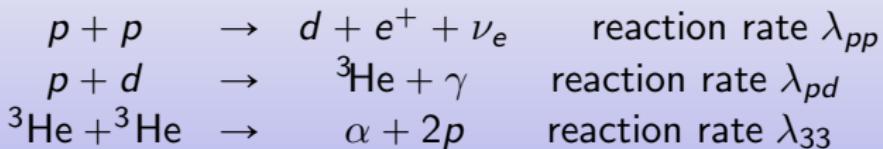

- Kawano, PArthENoPE - original Wagoner/Hoyle code and clones, <http://parthenope.na.infn.it/>
- Alter BBN, <https://alterbbn.hepforge.org/>
- PRIMAT - Mathematica code,
<https://arxiv.org/abs/1801.08023>
- F.X.Timmes BBN code,
http://cococubed.asu.edu/code_pages/net_bigbang.shtml

Experiments devoted to improve low-energy cross-sections, e.g:

- ① LUNA (Laboratory for Underground Nuclear Astrophysics),
Laboratori Nazionali del Gran Sasso (LNGS), Italy

Hydrogen burning: *ppl* cycle

Kinetic equations:

$$\begin{aligned}\dot{n}_p &= -2\lambda_{pp}n_p^2 - \lambda_{pd}n_p n_d + 2\lambda_{33}n_3^2 \\ \dot{n}_d &= +\lambda_{pp}n_p^2 - \lambda_{pd}n_p n_d \\ \dot{n}_3 &= +\lambda_{pd}n_p n_d - 2\lambda_{33}n_3^2 \\ \dot{n}_\alpha &= \lambda_{33}n_3^2\end{aligned}$$

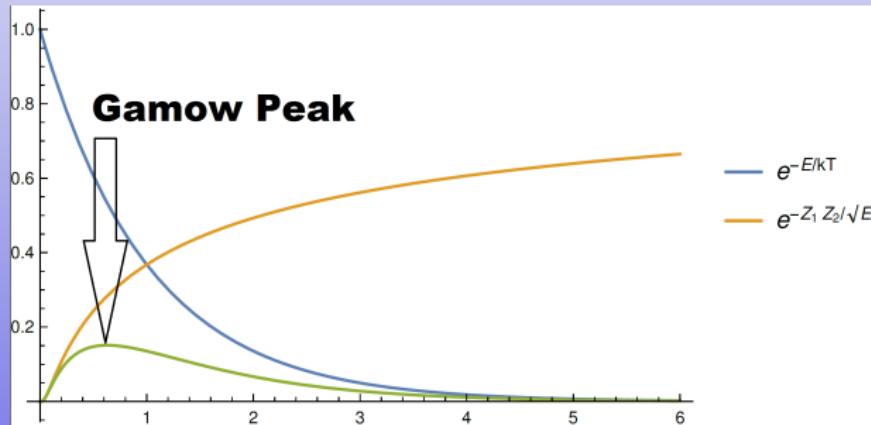

Baryon number conservation:

$$\sum_{i=1}^4 A_i n_i = n_p + 2n_d + 3n_3 + 4n_\alpha = \text{const},$$

$$\dot{n}_p + 2\dot{n}_d + 3\dot{n}_3 + 4\dot{n}_\alpha = 0.$$

From cross-section/S-factor to reaction rate

$$\lambda \propto \int_0^{\infty} e^{-\frac{E}{kT}} \sigma(E) E dE = \int_0^{\infty} e^{-\frac{E}{kT}} \frac{S(E)}{E} e^{-2\pi\eta} E dE$$

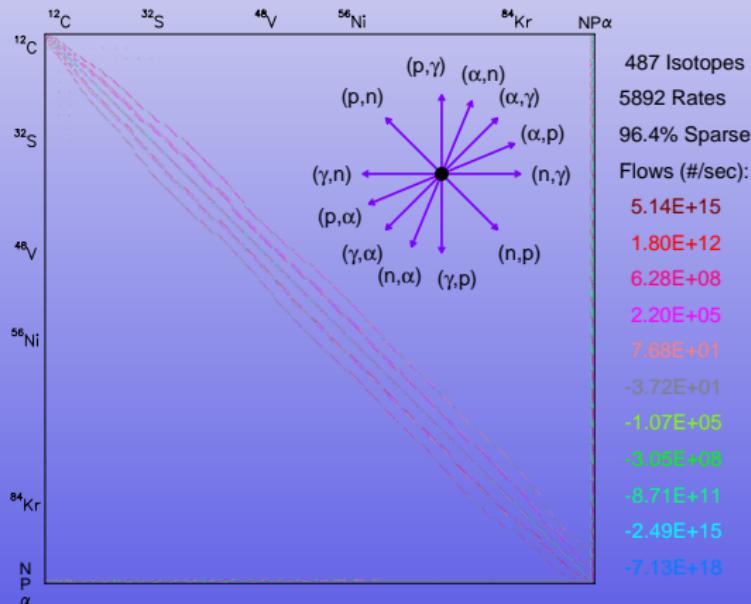

- Boltzmann distribution $e^{-\frac{E}{kT}}$ (thermal energy tail)
- Sommerfeld parameter ($v = \sqrt{2E/m}$ - relative velocity): (quantum electrostatic barrier tunneling)

$$\eta = \alpha \frac{Z_1 Z_2}{v/c} = \frac{Z_1 Z_2}{2\epsilon_0 v}$$

General nuclear burning: hardwired vs soft-wired

With increased amount of measured/computed nuclei and cross-sections reaction networks become prohibitively complicated and poorly understood. **Statistical methods can help!**

See e.g. http://cococubed.asu.edu/code_pages/net_torch.shtml

Nuclear Statistical Equilibrium

- idea dates back to F. Hoyle, „nuclear statistical mechanics”

„*The synthesis of the elements from hydrogen*”, MNRAS, 106 (1946) 343.

- Hoyle proposed two pathways to nucleosynthesis theory:
 - ① find equilibrium for **known** objects [in 1946 just stars]
 - ② analyze whole $T - \rho$ plane, select interesting regions **then** look for appropriate phenomena in cosmos [now: stars, thermonuclear & core-collapse supernovae, novae, X-ray bursts, NS-NS mergers, Big Bang, cosmic-ray, ...?]
- P. Holfich coined „stellar amnesia” idea - regardless of complicated history matter finish in equilibrium state
- in famous B²FH article *Synthesis of the Elements in Stars*, E. Burbridge, G. Burbridge, W. Fowler, F. Hoyle, Rev. Mod. Phys. 29 (1957) 547 NSE is referred to as **e-Process**.
- above article established **Nuclear Astrophysics** as separate branch of physics; many nuclear physicists retrained as astrophysicists, incl. H. Bethe and many our colleagues here in Cracov e.g. K. Grotowski

- ① Full equilibrium determined by 2 parameters T and ρ only (baryon number B and electric charge Q conservation) is very rare, because of properties of *neutrinos*.
- ② additional parameter is required, related to [electron] lepton number L_e conservation
- ③ usually it is either **neutron excess** η or lepton-to-baryon number ratio Y_e :

$$\eta = \frac{N_n - N_p}{N_B}, \quad Y_e = \frac{N_e}{N_B} \equiv \frac{N_p}{N_B}, \quad \eta = 1 - 2Y_e$$

- ④ Y_e is assumed constant because:
 - ① slow weak interactions compared to strong interactions
 - ② kinetic β equilibrium: identical ν_e and $\bar{\nu}_e$ emission

$$\sum_{k=0}^{N_{iso}} X_k = 1 \quad (1a)$$

$$\sum_{k=0}^{N_{iso}} \frac{Z_k}{A_k} X_k = Y_e \quad (1b)$$

Abundance X_k k -th nuclide of atomic number Z_k and mass number A_k :

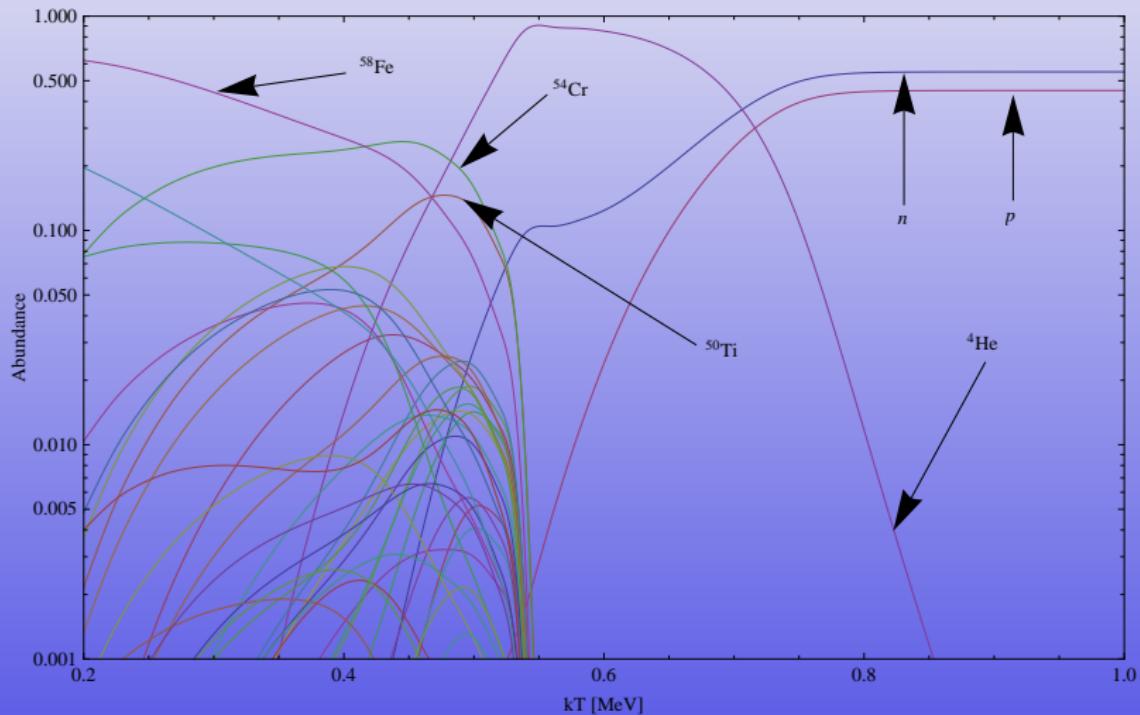

$$X_k = \frac{1}{2} G_k(T) \left(\frac{1}{2} \rho N_A \lambda^3 \right)^{A_k-1} A_k^{5/2} X_n^{A_k-Z_k} X_p^{Z_k} e^{\frac{Q_k}{kT}}. \quad (2)$$

Temperature-dependent partition function:

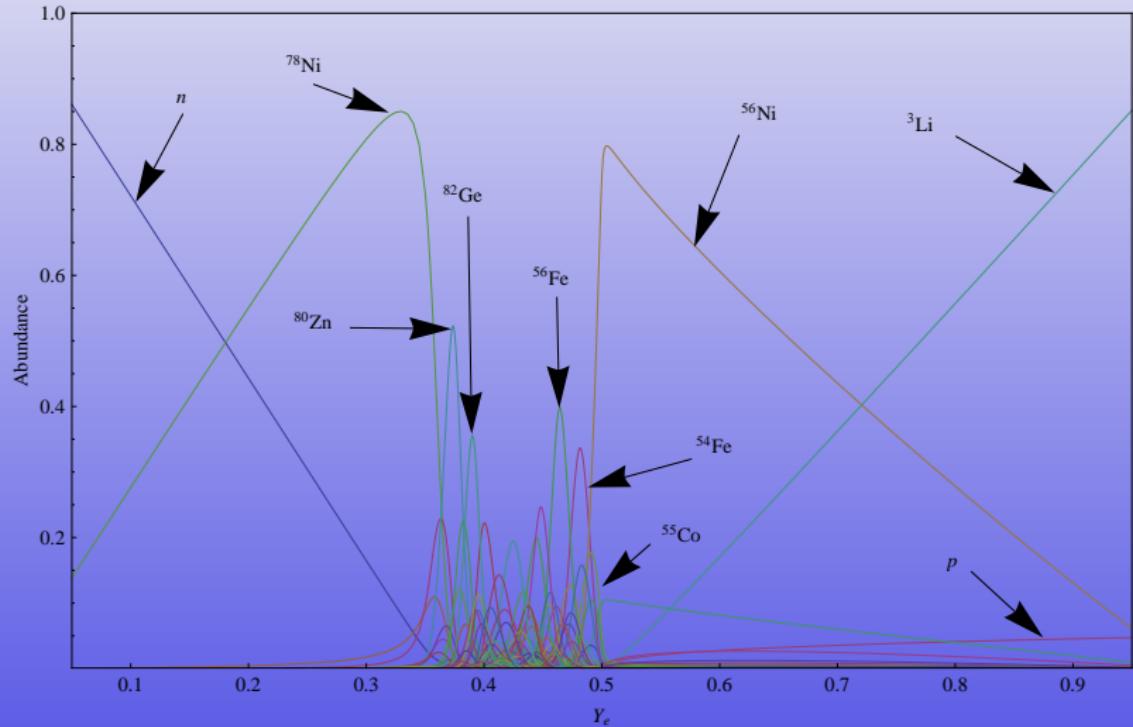

$$G_k(T) = \sum_{i=0}^{i_{max}} (2J_{ik} + 1) e^{-\frac{E_{ik}}{kT}} \quad (3)$$

- ➊ two unknowns: proton and neutron abundance X_p and X_n
- ➋ very high order polynomial system (up to X^A , e.g. ^{238}U)
- ➌ basic nuclear structure enough:
 - ➎ nuclear mass or binding energy
 - ➏ ground state spin
 - ➐ excited energy levels and spins
- ➍ input variables: $T - \rho - Y_e$ triad

$Y_e = 0.45, \lg \rho = 6 \text{ [g/cm}^3\text{]}$

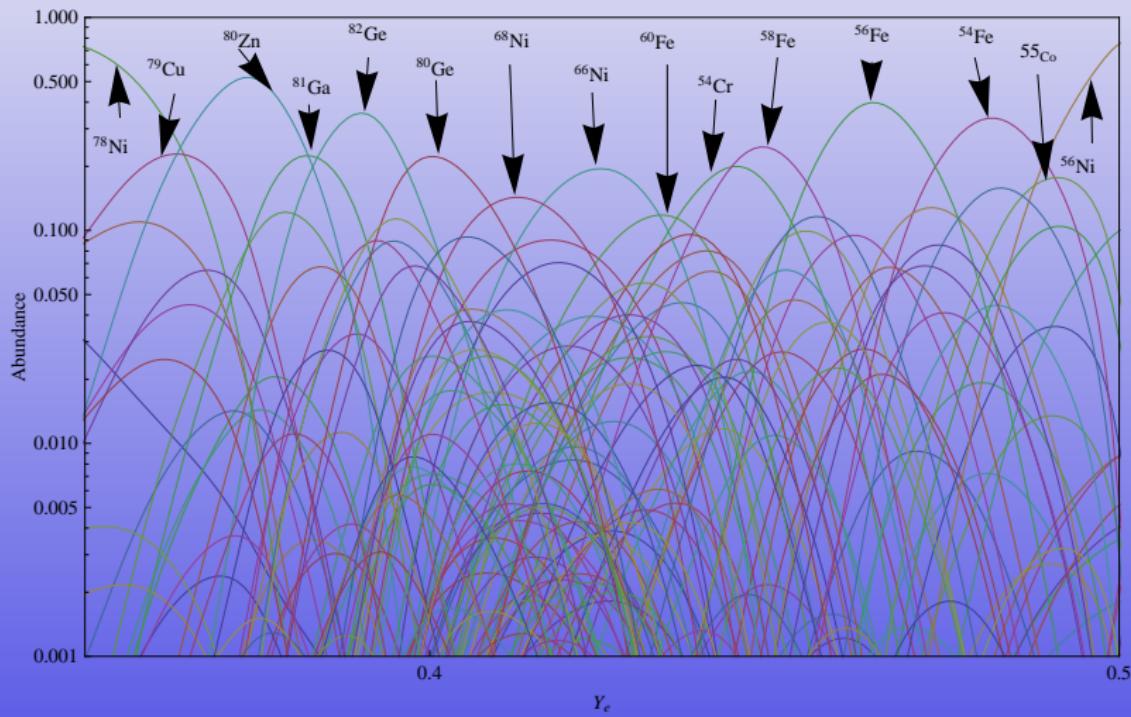

kT=0.5 MeV, lg ρ =10 [g/cm³]

NSE: viewgraphs

$kT=0.5 \text{ MeV}$, $\lg \rho=10 \text{ [g/cm}^3\text{]}$

Explosive phenomena in the Universe

- ① either by kinetic equations or equilibrium methods we are able to find conditions responsible for a subset of produced nuclei
- ② most sites are now established
- ③ it is not enough to produce elements — they must be ejected/spread into the Galaxy
- ④ we must enter formidable area of numerical simulations of **supernovae, novae**, compact object (black holes, neutron stars, white dwarfs) **mergers** and accretion disks
- ⑤ nuclear physics provides essential input data in form of:
 - nuclear cross-sections / reaction rates
 - binding energies and structure of nuclei
 - weak interaction rates (β decays, e^\pm captures)
 - last but not least: **Equation Of State** for nuclear matter

Supernovae

Two physical types of supernova

Given two known primary sources of energy in the Universe:

- ① **Thermonuclear** supernova - nuclear explosion or even detonation of the whole star [Type Ia, PISN?]
- ② **Core-Collapse** supernova - gravitational collapse of the central region of the star [Type Ib/c, II, long-GRB]

Crash-course in stellar evolution:

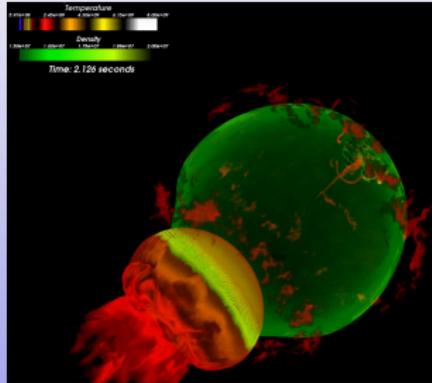

- burn $H \rightarrow He \rightarrow C/O \rightarrow$ „iron” as far as initial mass goes UP
- if $M < M_{\odot}$ He white dwarf forms with $M < M_{\odot}$
- if $1M_{\odot} < M < 8M_{\odot}$ C/O white dwarf forms with $M \simeq M_{\odot}$
- if $M > 8M_{\odot}$ iron white dwarf forms at the center with $M_{\odot} < M_{Fe} < 2M_{\odot}$ and subsequently collapse to **neutron star**
- if $M \gg 25M_{\odot}$ quiet collapse to a black hole of a whole star [or possibly thermonuclear explosion of massive C/O core]

Type Ia (thermonuclear) supernova

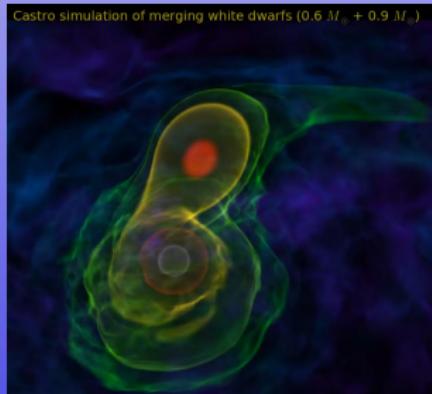

- ① every white dwarf is a ticking unexploded bomb waiting for $\sim 10^9$ years for explosion
- ② slow-match fuse is either accretion from companion star in binary system, or emission of gravitational waves
- ③ after ignition mass threshold, explosive thermonuclear burning front incinerate whole star in few seconds

Deflagration-Detonation Transition: click:[D-D-T]

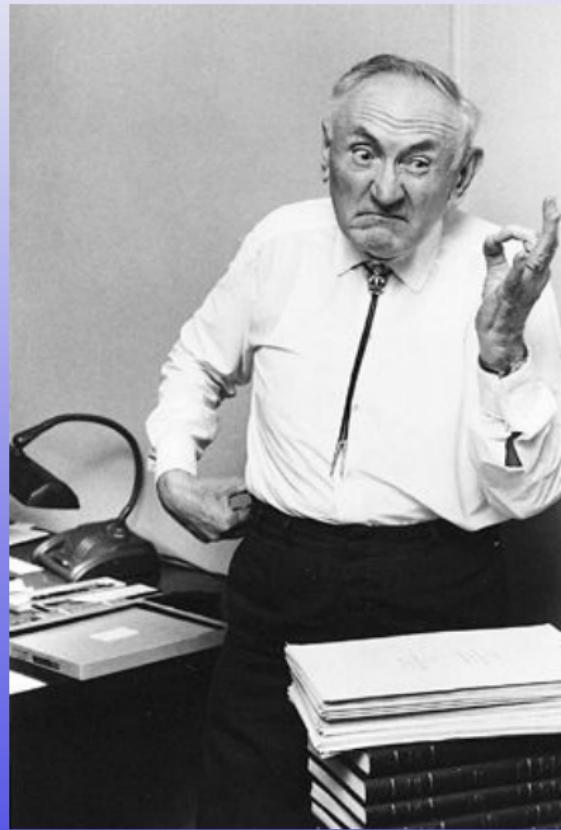

White dwarf merger: click:[WD Merger]

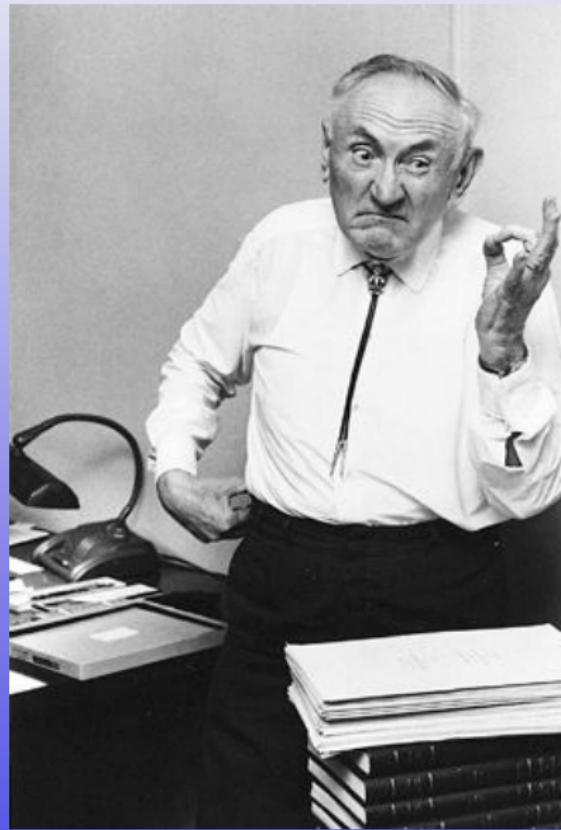

[Core-Collapse] Super-Nova

- Baade&Zwicky (1930-40) find and name several supernovae
- final distinction between classical novae [Galactic] and super-novae [extragalactic]
- they correctly (!) guess physical explosion mechanism: collapse to pure neutron object (neutron discovery: 1932)
- finally super-nova becomes supernova
- true Zwicky's motivation for name still mystery

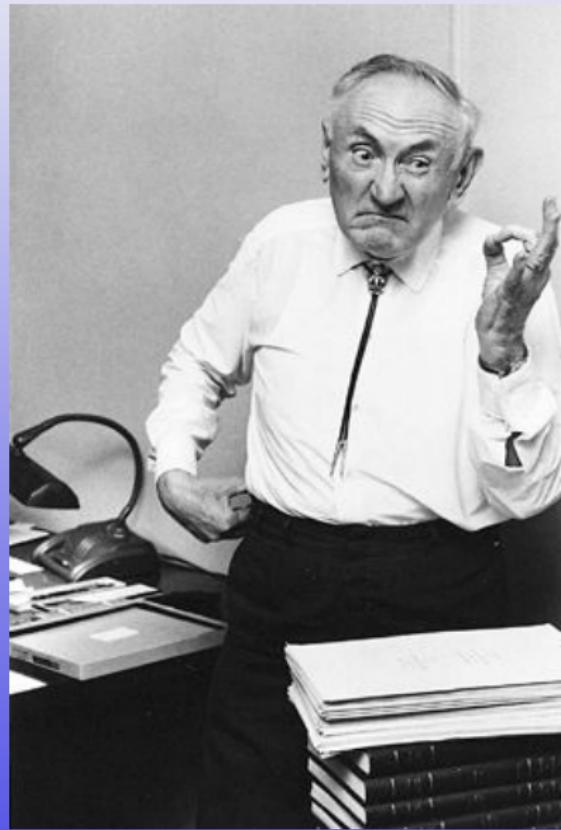

[Core-Collapse] Super-Nova

Supernova problem

- ① so-called prompt supernova mechanism generally **do not work**, except for very soft EOS ($K \ll 200$ MeV) and low-end stellar mass ($8M_{\odot} < M < 11M_{\odot}$ with O-Ne-Mg core)
- ② in typical situation shock retreat with infalling envelope with no explosion at all [quiet collapse]
- ③ above is in contradiction to hundreds of observed supernova events every year

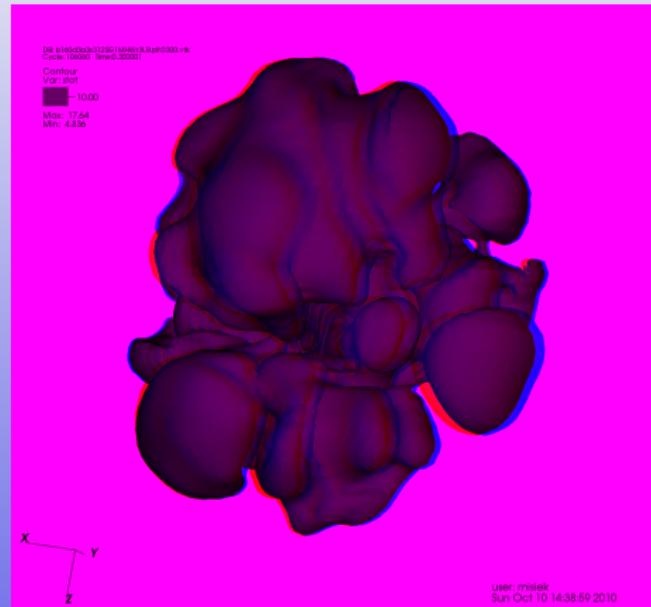

Possible solutions include:

- neutrino mechanism
- 2D/3D turbulence/ SASI
- neutron star rocket effect
- magnetic/rotation/jet
[supernova remnants with ears]

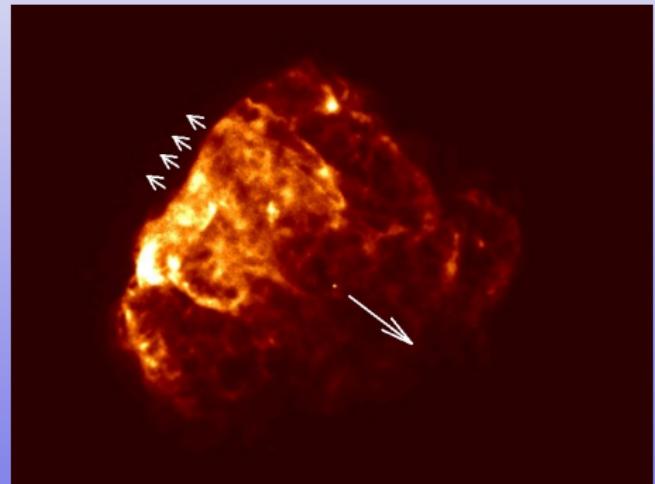

Possible solutions include:

Conclusions

- ① connection and influence from/to nuclear physics ↔ astrophysics still strong
- ② active research area related to *r*-process (**Neutron Star mergers**) and *rp*-process (explosive H burning)
- ③ huge amount of cross-sections, weak rates, masses measured and computed (incl. radioactive) ...
- ④ ... but a lot of effort required to use them, including purely technical/IT problems
- ⑤ significant lag between experimental knowledge (e.g. nuclear EOS, neutrino oscillations) and full astrophysical implementation still persists due to historical reasons and legacy codes

Thank you!

Beyond simple H burning

- H-burn in the Sun (pp-cycles) is well understood and experimentally confirmed (cf. our Borexino team)
- CNO-cycle (catalyzed) is well understood, but CNO-neutrinos still not confirmed
- standard CNO powers stars more massive than $2 M_{\odot}$
- hot-CNO (explosive H burning) powers classical novae and X-ray bursts
- explosion is a result of H accumulation on surface of compact degenerate object: **white dwarf** or **neutron star**
- rp-process (rapid proton capture) operates at $T > 10^9$ K
- reaction networks become complicated and might involve *short-lived α -unstable nuclei*
- another intriguing case is H-burning in first stars after Big Bang
- yet another unexplored idea is antineutrino-accelerated hot H-burning:
